ABSTRACT

This reference design details IEC ESD, EFT, Surge Protected and AC- coupling of RS-485 signals. Although this signal is always typically DC coupled which are using AC-coupling has several advantages. AC-coupling allows many transceivers to operate with the wide/large common-mode offsets, enabling wide/long-distance communication without routing an additional ground wire. This protection is useful in industry based application that requires data transfers across wide distances with a minimum number of wires. Industrial based network services such as RS-485 are expected to withstand/sustain harsh system oriented transient levels in their final end applications without getting damaged. This event process will be caused due to electrostatic discharging process during handling and inductive load interruption and/or relay bounce contact or strikes of lighting. TIDA-00731 shows the practical example which is used to protect the most sensitive components which are against their lethal transients. This project moves through the following such as TIA/EIA-485 standards and the IEC 61000-4-x transient test standards and the implementation of system-level protection level which are against the transients and overall schematic layout designs.

I.INTRODUCTION

Our integrated circuits defines on the basics reference pictorial representation of network combination allow us to create a revolutionary which will be the next-generation intrusion control panel system design in both wired and wireless connectivity circuit applications, advanced sensing with low power, new human machine interface technologies with high efficiency and highly confidential security features. Intrusion control panels based applications often requires of multiple communication protocols on wired on the circuit connection establishment with both Ethernet and RS-485 and wireless interfaces in which has highly efficient able multi- stage power tree with the mode of battery charge and gauging to enable for at least 24 hours operation on power backup connection using product such as battery which gives the ability to reducing false alarms using multiple sensors input which provides two-way audio communication and control with cloud intelligence. The access control term system refers to the process of practicing the method to restrict the entrance to a specific task or device such as either specific properties or making the recognized members to make a control of it and mode of battery charge is increased to make life long time with huge efficiency to increase more devices in controlling.

A Access Control System has being targeted someone to use by a person may be whether bounce person or a reception women in the process of mechanical form which has both clasp and keys. Within specific environmental surroundings, management of corporal keys has to be plotted in the action of monitoring and maintaining procedure in the mechanical process to remote areas. Physical operating control system can be referred in term matter of whom, where and when, The Access Control a system acquires the process by who was allowed either enters else exits. There are allowed to permit quit or continue. Also, they are accomplishing on using both latches and flips. Mechanical type locks and keys do not needed for any record of the keys or locks which can be helped for any specific application and devices may be whether quite possible photo printed a network which has to transfer to a unrecognized person.

II.ANALYSIS

The major steps to be carried out in the process of designing the printed circuit board has initiated with designing the specifications of the final end product shaped model and moves along the document in

which saves away the format created of database which allows next coming changes of reproduction of documentations that may be needed to confirm production of on moving results. The process makes assessing the completely computer-oriented tools which has been made to perform “right the first time”. A initial process is more often quite to create whether an analog or digital printed mother boards. The difference among the designing procedure for both two different brands on uncommon is the complex between two types of circuits.

III.DESIGN

The main aim is to prefer a designer’s choice to wish for a PCB circuit that includes total group of working networks which functions having the similar variations results plotting in the format of graphs of plotting conducting values and speed of transmission and tolerating the need of materials where the range of temperature varies on the validating the power supply voltage and so on.

3.1. CREATE SYSTEM SPECIFICATION:

A System Specification gives the needed outcome to satisfy the needs of response and a complete out coming product model.

3.2. SYSTEM BLOCK DIAGRAM:

The block diagram of a PCB board gives the outline circuit connection that provides the arrangement of multi component to be placed on correct spot locations.

3.3. PARITON SYSTEM INTO PCBs:

The circuit connections are spliced into multiple PCB assembly circuit lines, looping the similar components have same function that works together in a single board.

3.4. PCB DETERMINES PCB SIZES:

The locale and dimension has to be sketched, frequently by increasing number of layers in between them.

3.5. CREATE SCHEMATICS:

Schematics and block diagram are the initial process to make an outline model on base of application product.

3.6. BUILD COMPONENT LIBRARIES:

Tools information has stored in a datasheet of library else group of library files in a database single ingress such as Type, Size, Function, Characteristics and so.

3.7. SIMULATE DESIGN:

Design of model has to be checked before large scale production to check the product satisfies the needs given by the clients for their usage purpose.

3.8. PLACE COMPONENTS ON PCBs:

The components are plotted on multiple layers to check the efficiency and usage of board.

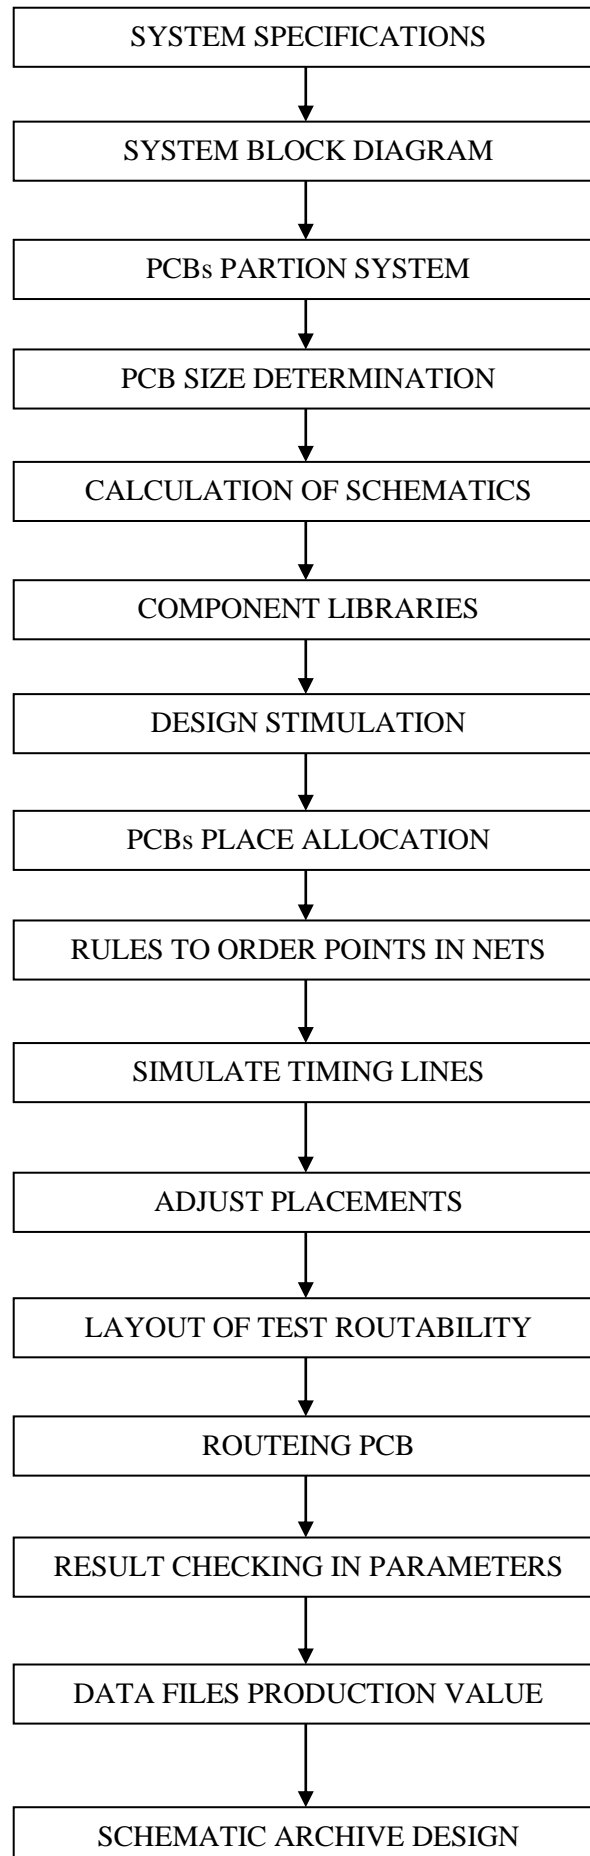

3.9. ORDER POINTS IN NETS TO RULES:

It is important to plot the circuit network connections among the loads of terminations with drivers on precise the fast-moving phenomenon.

3.10. SIMULATE TIMING AND TRANSMISION LINES:

The output return values are to be checked in regular coincide in stimulation process of output gathering and the transmission lines among the components are shorted to save the PCB board place which help to add more applications.

DESIGN OF INTRUSION CONTROL PANEL

3.11 ADJUST ORDERING AND PLACEMENT:

The placement is most important step which is used to check the arrangements in proper order to minimize that may increase the number of applications on it.

3.12 TEST ROUTABILITY AND LAYOUT:

Most issue takes on PCB designing will take place on testing it. Most of the problems rise while during because of line soldering mismatch or shorted.

3.13 ROUTE PCB:

It makes in a mixture of designing the routing specific signals that may automatically routing the rest of it.

3.14 CHECK RESULT AGAINST SPECIFICATIONS:

The algorithm final testing in Gerber Data performance to confirm which has spread of line makes the amount of volt transmitting and spacing rules to avoid calibration.

3.15 GENERATE PRODUCTION DATA FILES:

It is one of the most important in which most unwanted materials are to be eliminated that may give space to add more components instead of it.

3.16 ARCHIVE DESIGN:

The design data base will be saved in a specific library and that will be takes from list of bill of materials and it is used to achieve design.

IV.DEVELOPMENT

Once of all upcoming process, manufacturing data has been processed, the designed database with manufacturing data structures which are saved on either the magnetic tape roles else some distinct for further succeeding usage in producing some assimilate switches and retiring on moving events from specific folders that are designed and drawing resaved for the manufacturing are either lost or destroyed.

V.IMPLEMENTATION

Intrusion control panel decreases the component size of PCB layer circuits based implicational devices in residential ,commercial and industrial machineries in some specific system with multiple device connected oriented main hub connecting board is interconnected. Most connections in industries consist of multiple layers oriented meters. Every rotation is directly related to a capacity of processed data.

Once proper mode is enabled automatically, the device functionality will be checked via using these three pin berg header labeled R which is called as receiver pin, these three pin berg headers labeled D which is called as driver pin, and the bus pins via single terminal berg pins labeled A and B. When device functionality is verified, the transient testing can be done via the two banana jacks connected to the bus pins. Those tests are meant to simulate transients caused by either direct or indirect lightning strikes as well as switching of multiple power system including both load changes and short circuits. These tests results require both five either positive or negative surge pulses with a time intervals between pulses of one minute.

VI.EVALUATION

The result of the PCB designing sequence in which may be seen during the process takes long from the theme in all the possibilities through the process of fabrication in both assembly and testing. A computer-based application which has interrupted in either automate or improving the speed and accuracy of each steps using in this process. The tools had been divided into many groupings based on where they can be used on the tools:

- CAE's applications
- CAD's applications
- CAM's applications

It is taken from the titles of the tools that they can help in circuit designs, physical layout of mother circuit and Manu facts of the bare PCB and the PCB assembly.

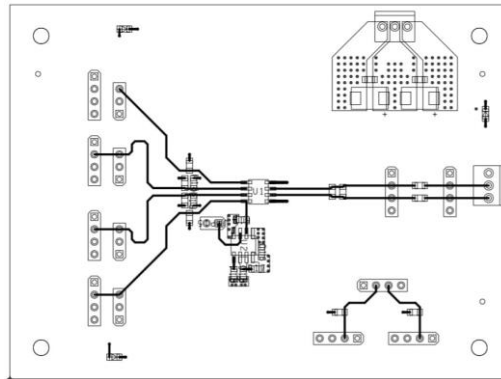

FIG 7.6 : PCB CONNECTION PLOT DESIGN

VIII.CONCLUSION

The discovery of PCB that hold ups corporeal electronic components and their wiring through the surface based mounted using copper is really astonishing. An intrinsic part of the plan of the whole product and it can be the key to achievement of the product. With the expansion of smart water meter innovation as involuntary meters with gingerly increasing restored by smart or dynamometer. Millimeter based water meters blends some electrical sensors in processing negligent water meters. A ordinarily based sensors like breeding switches, Hall-effect sensors or photoelectrical code registers. Next processing refinement during micro sized controller units in processing electronica modeled motherboards. The flow of water is assigned as data format in datasheet which are imparted to the LCD or result of the statistics management arrangement.
